Abstract

Background and Aims: DNA constructs containing HCV antigens have become one of the vaccine candidates for induction of anti-HCV cellular and humoral immunity. In this study, we constructed a novel expressing vector harboring a fusion sequence derived from an overlapping fragment in the middle of NS3 and a truncated core fragment to avoid troubles reported to be associated with full gene expression.

Methods: The partial NS3 (pNS3) and core genes were amplified by RT-PCR method using serum of HCV infected patient harboring genotype 1a of virus. After purification and cloning the genes into TA-cloning vector, they were evaluated by sequencing and restriction digestion analysis. The resultant pNS3 and core gene subcloned into expression vector separately followed by expression evaluation using RT-PCR and western blotting. The core expressing vector exploited for amplification of a new truncated core (50-160aa) sequence using PCR. Truncated core fragment was first cloned into TA vector at a natural restriction site downstream of pNS3 fragment. The resulting fused sequence was cut and subcloned into expression vector. The integrity and ability of expression of this fused sequence was evaluated by sequencing followed by RT-PCR analysis after DNA transfection into 293 cells.

Results: The repeated sequencing data showed sequence integrity among the gene fragments as well as homology among them and reference 1a sequences. The colony-PCR, RT-PCR and western blotting confirmed insertion of genes into expressing vector, expression of genes in 293 cell line and production of protein in 293 respectively.

Conclusion: This new expressing vector harboring a novel fused fragments of NS3 and core genes may overcome shortcomings in vaccine design in the setting of HCV disease.

Keywords: Viral Hepatitis Vaccines; NS3; core gene

Introduction

Design and preparation of effective therapeutic and/or prophylactic vaccine for resolving Hepatitis C virus infection remains a big challenge but improving area of vaccine development. Due to the importance of cellular immune responses, development of effective immunogens with the ability to induce both CD4+ and CD8+ T cell responses against HCV is an essential task in combating this virus (1, 2).

DNA based vaccines have been shown to evoke a suitable and long lasting T-cell

responses against a number of viral immunogens especially HCV antigens and are currently being used for vaccine trials in humans (3-5). DNA immunization methods are growing for prophylactic or therapeutic purposes in HCV infection. Two DNA vaccine candidates have already reached clinical evaluation, and are well tolerated and immunogenic in HCV-chronically infected individuals (5-9). Rather than the big advantages in comparison with other vaccine formulation, the ability to introduce virus antigen to the host immune system, enabling it to elicit strong Th1 type CD4+ T cells and CD8+ cytotoxic T cells, is an important feature of DNA immunization (5, 9). In DNA immunization procedure, by intracellular expression of recombinant HCV proteins, antigens would be endogenously synthesized and processed via MHC class I pathway and presented on the cell surface similar to that of natural infection (7, 10).

Non-structural protein 3 (NS3) is a relatively conserved protein with both protease and RNA helicase enzymatic activities (11). Previous publications showed that HCV specific cellular immune responses against NS3 is associated with viral clearance in acute infection, whereas absence of T cell response leads to viral persistence (12). Thus, NS3 is an important option for the purpose of anti-HCV vaccine design (4, 6, 7, 10, 13, 14). Theoretically, endogenously expressed NS3 protein may disrupt the functional integrity of antigen presenting cells (APCs) due to its protease and/or helicase enzymatic activity (15-17). Therefore, removing or reducing the protease function from NS3 may also be a way to boost immune induction by avoiding enzymatic function in APCs (18).

HCV core protein is the most conserved antigen among different HCV genotypes and immunization with this protein has resulted in induction of specific antibody and cytotoxic T lymphocyte (CTL) responses (12). Some previous studies have evaluated induction of immune response by core gene as an immunogen (12, 19-23). However recently published studies demonstrated that both C-

and N-terminal domain of HCV core contain autoimmune inducing sequences that maybe harmful for vaccine design (24). Also other studies had shown the immune suppression effect of core protein in animal models and defect of full core gene on immune induction in addition to usefulness of truncated form of core for vaccine purposes (18, 25-29). In this project, we prepared new expressing vector containing a truncated core gene without N- and C-terminal domain to avoid autoimmunity and/or immune modulatory effects of full length gene.

Therefore, constructing the DNA vaccine expressing specific parts of HCV antigens like overlapping middle region of NS3 or truncated core genes may overcome the present shortcomings of full length genes expression in order to avoid the autoimmunity, immune modulatory and other probably shortcoming effects of the full length protein in APCs. In this project, our aim was to design, construct and confirm a DNA construct containing fusion of novel overlapping region of NS3 with truncated core genes for future vaccine purposes as demonstrated in a schematic form in figure 1.

Methods

Reagents, vectors and cell Lines

The restriction enzymes (*NdeI, BglII*), *InsTAclone™* PCR Cloning kit, *Pfu* DNA polymerase in addition to other routine molecular reagents prepared from Fermentas company(Slovenia)**.** Plasmid and DNA isolation/purification kit from Bioneer (S.Korea), and Lipofectamin™ 2000 from Invitrogen (USA), culture media and other culture related materials prepared from Gibco (USA). All primary antibodies were purchased from Abcam Company and stored at -70°C for long time storage.

pAdenovator-CMV5-IRES-EGFP expression vector was purchased from Qbiogene Corporation.The Low-passage HEK 293 cell line was provided from National Cell Bank of Iran, were grown in Dulbecco's modified

Gene amplification by Reverse Transcription-Polymerase chain reaction (RT-PCR)

New overlapping region of NS3 gene covering incomplete protease/helicase domains (aa 1095-1387) of HCV genotype 1a was amplified and well characterized elsewhere previously (30). In the case of core gene similar method was employed for amplification. For Primer design, HCV reference sequences obtained from gene bank then by utilization of Generunner and Mega4 softwares, after multiple alignment 2 pairs of primers were selected for amplification of full core (aa 1-197) and 2 additional ones for new truncated core fragments, pCore (aa 50-160). The primers so designed to avoid false amplification of similar sequences from other HCV genotypes. Also, *BglII* or *NdeI* restriction sites, a stop codon (TGA) and a protein expression initiation codon (ATG) were introduced at both ends of primers for further manipulation. Also as a Glycin codon, GGT trinucleotides were inserted into primer backbone in the case of pcore-NdeF primer to make NS3-core fusion sequence (Table 1).

Four Iranian patients infected with genotype 1 of HCV were enrolled for screening in the study. The sera had been confirmed as HCV positive sample and genotype 1 in Shariati Hospital, Gastroenterology and Hepatology Research Center, Tehran. Viral RNA extracted by viral RNA extraction kit based on recommended protocol and RNA kept in -70°C until use.

First RT-PCR was done on four different extracted RNA samples using specific primer. After selection of one serum based on band density as the best sample, nested-PCR was developed to amplify a nearly 610 base pair sequence of full core.

PCR was performed in a total volume of 25 μl consisting of 0.2 μM each primer, *Pfu* DNA polymerase enzyme, and standard PCR constituents. The samples amplifed for 20 cycles in first round and 30 cycles for the second round at 60°C annealing temperature. The PCR products were then purified from the agarose gel using DNA Gel purification kit with respect to company instruction.

TA-genes Construction

The resulting extracted amplicons including full core gene was mixed with proper amount of pTZ57R/T cloning vector and ligation reaction was done as recommended by company with the help of T4 ligase. The ligation product was transformed into competent *DH5-α* bacteria and then the properly cloned core gene in pTZ57R/T vector (as a TA-core), were selected based on Blue/White screening and Ampicillin sensitivity on LB agar.

Insertion of gene into vector then was evaluated by colony-PCR using specific primers. The integrity of these constructs and

insertion of gene were assayed using restriction analysis with *BglII* and sequencing as well. To make sure that the construction and manipulation processes did not affect the base sequences of the gene, selected plasmids were submitted for bidirectional sequencing using specific primers by the application of an automated DNA Sequencer ABI PRISM® 3700DNA.

Construction of TA-NS3 vector described previously (30). These confirmed TA-core and TA-pNS3 vectors were digested by *BglII* followed by extraction of the single band of each gene from agarose gel using a gel extraction kit.

Expressing vector construction

The sequences of core and pNS3 gene fragments were digested and purified then were mixed with high pure linearized *pAdenovator-CMV5-IRES-EGFP,* an *IRES* *e*xpressing vector and the ligation reaction drove them to join covalently together by exploiting T4 ligase and also pretreatment with alkaline phosphatase. This vector contains strong CMV enhancer-promoter to drive substantial expression of genes of interest as well as an IRES sequence that induced GFP expression as a marker for transfection efficiency as well as evaluation of gene expression. The best constructs in bacteria were selected based on *kanamycin* resistance, Colony PCR and restriction analysis by *BglII* and designated as IR-core and IR-pNS3.

A new truncated core sequence harboring amino acid sequence 50-160 that is both N- and C-terminal domains deleted fragment prepared by PCR amplification on a TA-core and was named pCore. Briefly, 2 pairs of primers entitled pCore-Bgl and pCore-Nde (Table 1) exploited in 30 cycles standard PCR on TA-core containing full core and then the resultant amplicons prepared by core160-Bgl primers inserted directly into the IRES expressing vector. Also in addition to introduced *NdeI* restriction site at the ends of pCore-Nde primer, an additional GT nucleotide designed next to the coding sequence that added a new glycin code between pNS3 and pCore sequence as a spacer. These amplicons as well as TA-pNS3 were

digested by NdeI enzyme following gel extraction. In ligation mixture as shown in figure 1, TA-pNS3 linear plasmid will accept purified pCore sequence at *NdeI* restriction site so that pCore sequence followed first ¾ pNS3 region with a glycin amino acid between them as the spacer and named as TA-pNS3pCore. The proper vector designated as TA-pNS3pCore were selected based on ampicillin resistance and colony PCR.

The resultant TA-pNS3pCore was digested by *BglII* restriction enzyme then purified fusion sequences were inserted into linear *IRES* expressing vector by using T4 ligase. The proper clones were selected based on kanamycin resistance and colony PCR.

In all screening experiments, a new primer specific for CMV promoter was also employed to assess the correct orientation of genes inside the IR-gene expressing vectors (Table 1). The orientation of genes in plasmids was verified by special touchdown PCR in 65-55°C annealing temperature range using CMV-promoter primer as forward and core4-R, pcoreBglR and pcoreNdeR primers as reverse ones for detection of IR-core, IR-pCore and IR-pNS3pCore, similar to IR-pNS3 described previously.

To ensure the fidelity of the final fusion sequences, the gene was digested with *BglII* enzyme and also introduced into an ABI PRISM® 3700DNA analyzer automated sequencer using a set of forward and reverse primers.

Blast analysis of sequences

For sequence analysis, edited sequences of 2 genes were extracted from received data then submitted to online Blast and alignment tools for better understanding the sequence. After alignment of prepared sequences with reference sequences from NCBI gene bank, the degree of homology and difference of genes and amino acids was estimated.

Analyses of gene expression

Transfection of plasmids into 293 cells. The 293 cells were propagated in DMEM, supplemented with 10% FCS and antibiotics (penicillin 50 U/ml and streptomycin 50 μg/ml) and all cultures were maintained at 37°C in a moist atmosphere containing 5% CO_2. They

seeded in 6 well plates the day before transfection so that at the transfection time they would reach to 70% confluency that is a marker for starting the logarithmic growth of the cells. Based on company instructions, a mixture of Lipofectamine 2000 and plasmid was prepared and then added to the cells gently. Following incubation at 37°C for 12 h, the cells were re-fed with fresh complete DMEM medium.

All expression vectors including IR-Core, IR-pNS3pCore and IR-pNS3 were transfected and compared with an empty plasmid as negative control for analysis of specific gene expression. These cells harvested up to 48 hours after transfection.

After brief screening by GFP expression under fluorescent microscopy, genomic RNA was extracted using total RNA extraction kit and Trizol method following DNase-I treatment to remove perturbing residual DNA and avoid false interpretation. Fluorescent images were captured at 490 nm using a Nikon Eclipse E1000 microscope after changing the medium with new DMEM and before harvesting the cells.

Reverse transcription. The 20 μl reaction mixture for each gene contained 5 μl of extracted RNA, 4 μl of 5X RT buffer, 2 μl dNTP (2.5 mM of each dNTPs), 1 μl (10 pmol/μl) of reverse or random hexamer primer, 0.5 μl (40 unit/μl) of RNase inhibitor, 1 μl (40 unit/μl) of M-muLV reverse transcriptase and 6.5 μl of RNase free distilled water. Reverse transcription was carried out at 42ºC for 50 min followed by incubation at 70ºC for 10 min. PCR was done with above corresponding specific primers for each gene. The reaction was performed in a total volume of 25 μl consisting of 0.5 μM each primer, *Taq* DNA polymerase, and standard PCR constituents. The samples were amplified for 35 cycles at 56° c annealing temperature. The PCR products were then run on 1% agarose gel.

Western Blotting. For SDS–PAGE analysis, cell lysate samples were mixed in SDS–gel sample buffer, containing 2% SDS and 2-mercaptoethanol and heated at 100 °C for 10 min. The proteins were separated in 12% SDS–polyacrylamide gels. Western blotting was performed as described earlier (31) using mouse monoclonal antibodies against core (aa 70-90) and commercially rabbit polyclonal antibodies for NS3. Proteins were blotted onto nitrocellulose membrane and it was blocked by incubation in 3% BSA in TBS buffer at 4^{0} C overnight and subsequently exposed to diluted primary antibodies in 10ml of TBS for 2 h. The membrane was washed, and then incubated in 10 ml of TBS containing 2 U HRP-labeled goat anti-rabbit IgG or rat anti-mouse IgG (Sigma–Aldrich Corp.). The membrane was washed as in the previous step and then the chromophore 3, 3-diaminobenzidine (DAB) was used in order to develop the color-based signal.

## Results

Amplification of genes
The electrophoretic results on agarose gel from RT-Nested-PCR product revealed 610 and 930 base pair fragments for full core and pNS3 amplification respectively. During preparation of truncated core from IR-core after standard PCR there was a 330 bp amplified fragment after colony PCR on IR-pNS3pCore and IR-pCore as screening tool (fig. 2). The primers for amplification of two core truncated forms were designed such that they would amplify probable immunogenic regions in addition to avoiding harmful or unnecessary sequences.

Blast analysis of sequences
For evaluation the fidelity of the sequences, all cloning and expression vectors were sequenced by an automated sequencer. The sequence analysis of the full core gene showed more than 99% similarity with those of other 1a sequences using multiple alignment survey by online blast software. It is presumed that core is the most conserved sequence among HCV
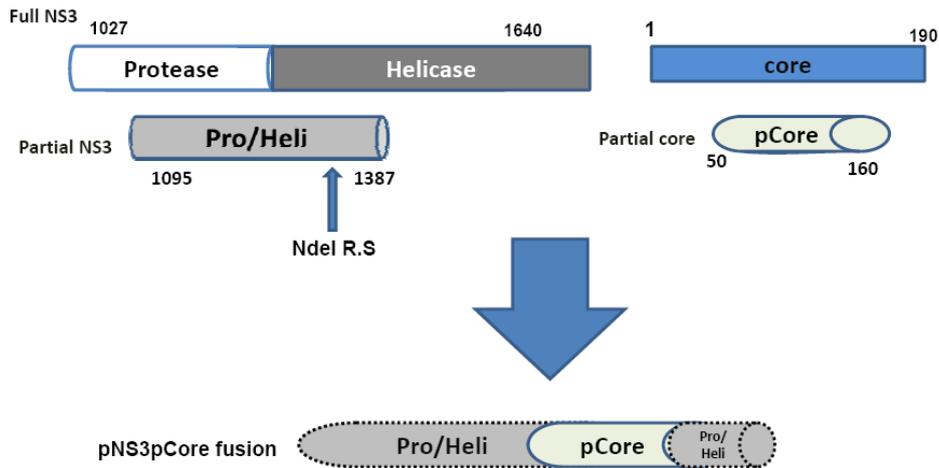

Fig. 1. Schematic representation of construction the novel fusion sequence including overlapping fragment of NS3 gene and N-, C-terminal deleted fragment of core gene. The truncated core inserted into naturally occurred *NdeI* restriction site near the ¼ end of pNS3 but did not disturb its reading frame.

genotypes and this data also confirmed it. High homology with H77 strain in analysis was significant. Phylogenetic analysis showed that NS3 sequence belonged to genotype 1a of HCV virus as demonstrated elsewhere (30).

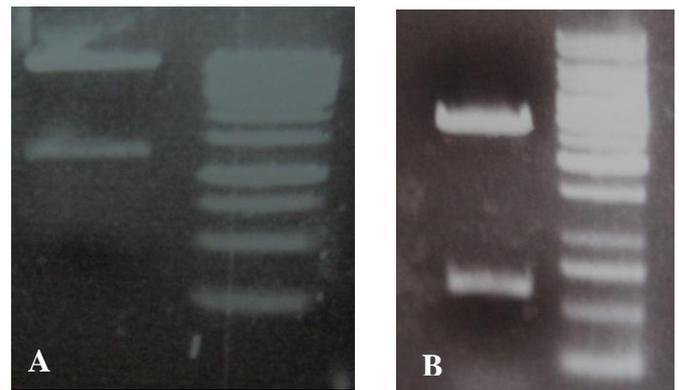

Fig. 3. Restriction analysis of of IR-pNS3pCore (A) and TA-core (B) vectors by *BglII*. (A) Digestion of IR-pNS3pCore by *BglII* showed a 1250 bp fragment as pNS3pCore fragment and vector backbone with near 9000 bp size. (B) Digestion of TA-core by *BglII* showed a 610 bp fragment in addition to TA vector backbone with near 3000 bp size. Marker: 1 kb ladder.

Expressing vector construction

The percentage of positive colonies in colony-PCR method during the screening was significantly high as we expected. The colony PCR showed amplification of 330 bp as presence of partial core in pNS3pCore fusion construct and 610 bp for full core as shown in figure 2 rather than 930 bp fragments for pNS3. Restriction analysis of corresponding IR-pNS3pCore and TA-core constructs by
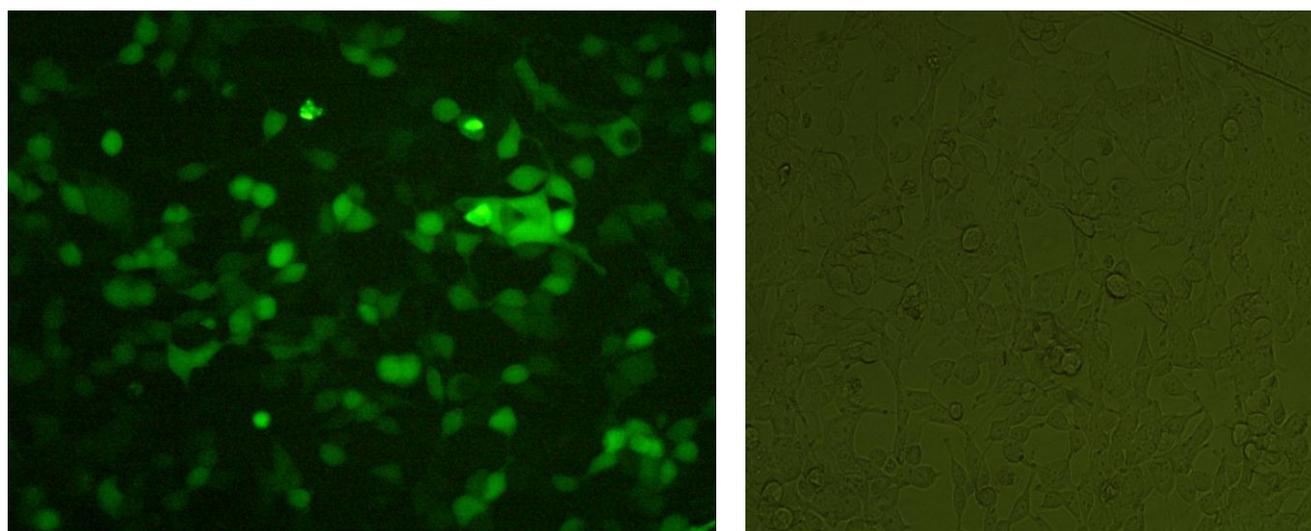

Fig. 4. GFP expression in 293 cells after transfection by IR-pNS3pCore in contrast to negative cells. After 2 days past transfection, fluorescent microscopy showed bright green in more than half of the cells as the sign of GFP expression, plasmid integrity and expression of gene of interest, fusion pNSpCore fragment.

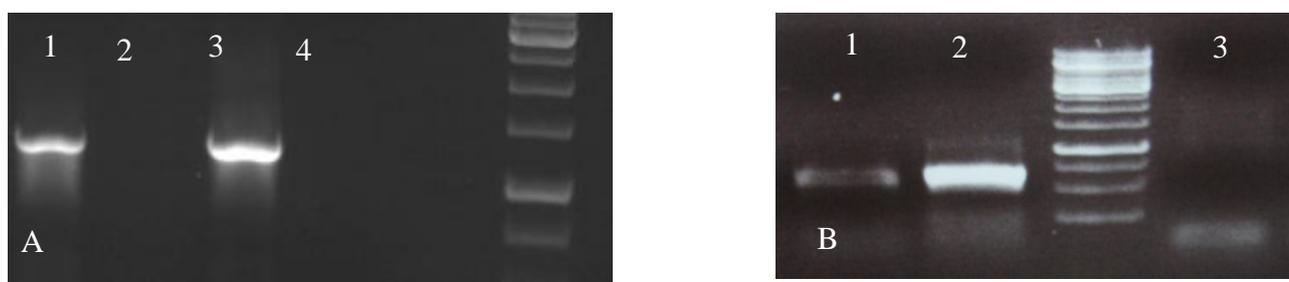

Fig. 5. RT-PCR results of gene expression by IR-pNS3pCore fusion construct (A) and IR-core (B). 293 cells transfected with a mixture of respected plasmid and lipofectamine 2000 then 2 days past transfection total RNA extracted and analyzed by RT-PCR.

promoter also employed to determine the correct orientation of genes inside the IRES expression vector. True amplification of right inserted gene inside the IRES plasmid made corresponding amplicons a little bigger than specific amplicons, with the sizes around 1150 bp for pNS3, 750 bp for core and 1350 bp for pNS3pCore fusion sequences after PCR (fig. 2).

Reverse transcription and fluorescent microscopy

At 2 days post transfection fluorescent images were captured by fluorescent microscopy. As shown in figure 4, about half of the cells showed the sign of GFP expression in compare to negative control that is nearly the indicator of gene expression as well.

Total RNA extracted from the 293 cell line showed suitable quality by detecting special common pattern for eukaryotic ribosomal RNA on the agarose gel. The RT-PCR results showed detectable expression of these genes that had been achieved after transfection of IRES expression vector containing gene fragments into 293 cell line. For IR-pNS3, IR-core and IR-pNS3pCore, there were the band sizes of 930, 610 and 1250 bp respectively as shown in figure 5. To avoid false positive, especial care was paid for removing the residual DNA to prevent misinterpreting the data.

Western Blotting

A low density but distinct protein bands were seen after Western blot analysis in cells transfected by IR-pNS3 (figure 6). The putative molecular weight of the protein was estimated to be approximately 30-31 kDa by SDS–PAGE, consistent with 70 kDa size for the full length sequence and also other similar studies (32).

In the case of core protein, a sharp band on 293 cells transfected with IR-Core expressing plasmids detected on membrane. As positive staining control, a purified core protein in concentration of 10ug was used that revealed a three band patterns demonstrating the 3 different expressed size of core in vitro.

Discussion

DNA Immunization has been shown to elicit suitable immune response against a number of viral antigens especially HCV and is currently used even for vaccine trials in humans (3, 7). The vectors expressing partial or full length of core and NS3 genes from HCV have been exploited for vaccine purposes routinely due to their suitable immunogenicity and high homology among HCV genotypes (3, 7, 33, 34).

Recent publications reported significant controversy regarding to usefulness of full length core protein as vaccine antigen (20, 21, 24, 26, 29, 35). Some groups of scientists started to use partial fragments of core gene instead of full length genome to overcome shortcomings reported to be associated with the full size core gene such as immunomodulatory and autoimmunity effects (18, 24, 26). In this project, we prepared a new expression vector containing core sequence without N- and C-terminal domain to avoid autoimmunity and/or immune modulatory effect of the core full gene sequence that was evaluated by others (24).

Because of both protease and helicase activities of HCV NS3 gene, theoretically, expression of its full protein in APCs may diminish the immune induction due to disruption of antigen processing or presentation pathway (17). So, we designed the NS3 primers in such a way that could amplify a new overlapping fragment covering both but incomplete domains based on a previously reported study (32). This sequence harbored CTL epitopes suitable for establishment of the cellular immune responses.

All of the primers used in this study were specifically designed for genotype 1 in order to prohibit false amplification of other sequences.

In order to better interpret the sequencing results, Blast analysis was carried out and it was shown high homology with references genotype 1a in both genes. The sequencing results showed a very high similarity between the amplified core genes with the other 1a reference sequences as expected for the most conserved genes.

RT-PCR and Western blot showed suitable expression of full core and pNS3 mother plasmids. RT-PCR also showed expression of fusion pNS3pCore fragments by expression plasmid. GFP screening assay confirmed the plasmids integrity and concomitant expression of proteins of interest in 293 cells.

In this work, new truncated core and an overlapping region covering incomplete helicase/protease of NS3 genes were amplified and fused together in an expression vector as a novel fusion construct. Theoretically, this new fusion vector containing the above sequences would be useful in future studies by avoiding hortcomings like the immunomodulatory/ autoimmunity effects usually associated with full length gene expression.
